

Using tech to fight forest fires

The South African forest fire season began a month ago, and an estimated 20,807 hectares of land were burnt in the Western Cape.

With such rampant and regular breakouts of forest fires, the quest to contain them before they cause widespread destruction, including property damage and loss of life, remains an issue of high importance for non-governmental organisations and the relevant government agencies.

Equally important is the need to safeguard against the loss of the lives of firefighters during missions to contain these blazes.

As this continues being an issue, mainly because of the dense vegetation found in the Western Cape, coupled with the dry weather that is typical for this time of the year, the need to use unmanned aircraft to fight fires is ever increasing.

Drones are particularly crucial for forest fires that tend to get out of control quickly and that put both pilots and crew at risk. There's only a small containment window between when the fire starts and when it gets out of control. Drones give firefighters a bird's eye view of the terrain and helps them determine where the fire moves next so they can swiftly make decisions about where crews should go and who should be evacuated.

If you're a firefighter responsible for forest fire response, mitigation and rescue, the benefits of drones are immense.

So, here are 4 ways we can use drones to fight fires:

• Drones gather situational awareness in a short time

A drone helps you decide within minutes the type and amount of resources to send to the scene. Some drones are also equipped with thermal sensors, which uses infrared radiation to help first responders locate heat signatures of humans and fire hotspots that show where fires are most likely to spread. Even before your personnel arrive on the scene, commanders are able to make decisions just from these images live-streamed to their computers.

In early December whilst fighting a blaze, SanParks made use of a DJI drone with an infrared camera to capture images of the Rocklands fire in Simonstown.

In a similar incident in the German town of Hechingen, firefighters had to fight against winds that were spreading to nearby wooded and populated areas. The creeks had dried out while the first fire truck that arrived carried only 2,000 litres of water.

Hechingen's Fire Brigade deployed DJI's Matrice 210 ruggedised commercial-grade drone, a Zenmuse XT thermal camera, and an X4S high definition visual imaging camera. These fed information to the incident commanders and helped them know where to direct their resources, how many units to send and where to increase water supply. In the end, the crew extinguished the blaze with only 5,000 litres of water mixed with compressed air foam. The drones not only helped them save water but more importantly hastened reaction time helping the Brigade send crews faster to the scene with the exact manpower, units and supplies.

Drones for real estate: What you need to know

Lisa Ellman and Matthew Clark 14 Jan 2020

"The biggest advantage came to light during the search for hotspots and extinguishing them," Hechingen's Fire Chief Commander Bulach later told DJI, "The simultaneous deployment of the XT and X4S provided me with exact information about where to delete the hotspots and how long until we reached a safe state."

• Drones protect your personnel

Drones help you monitor your crew to make sure you're sending them in the right direction, that they're safe and to help you determine whether to send backup forces.

On 13 August 2017, Yosemite firefighters battled a nine-day blaze in Southfork, California, that was complicated by weakened timber trees in the nearby region. Flying planes in the tight canyons was dangerous due to a billowing column of smoke.

At the same time, an unexpected thunderstorm spread the fire, blurring the firefighters' primary containment line and threatening to spread to nearby villages. The Yosemite fire-force used a DJI drone with the Zenmuse XT thermal payload in their pre-shift early morning hours to map fire lines and live stream information to controllers for operational decisions and situational awareness.

Tony Eggiman, Menlo Park FPD Fire Captain recalled, "the operations major told me later it brought his blood pressure from about 200 down to about 100. He was really happy."

With aerial intelligence captured by drones, incident commanders can make better-informed decisions that keep firefighters safe while they plunge into the fire and other dangerous spots to save other peoples' lives.

- **Drones enable fast mapping for incident response, as well as for post-incident recovery**

Drone solutions for forest fire response typically carry two different cameras: a visual camera and a thermal camera. The visual camera gives you a real-time view of different situations, able to easily spot things such as your fireteam or nearby equipment. The thermal camera scouts for heat signature of the human or fire hotspots.

Drones fly lower than helicopters, providing a more nuanced picture of the situation, and can navigate in tight or dangerous spaces where no helicopter pilot would dare to go. With thermal imaging capabilities, they can locate hotspots at a fire scene within seconds, and see people trapped even in areas of thick smoke.

Drones also play an important role after the fire has been put out. During the Carr Fire, crews piloted low-flying drones to capture 360-degree images of the destruction. For the residents forced out of their homes, this provided invaluable information on property damage to assess insurance claims in a faster time, letting victims more quickly take steps to rebuild their lives.

- **Drones give you accurate intelligence for informed decision making**

Wildfires often involve large-scale operations where the incident commander must make decisions on personnel and resource deployment. Drones are effective intelligence generators that can capture detailed data and information from the field, and live stream back to the command centre. By having that real-time aerial view, you can see exactly what's happening and don't have to rely on second-hand information. You know what's going on and where. You can also monitor your crew to see their location and that you're sending them in the right direction.

Drones allowed firefighters of the Gaoming district, Foshan in South China to expertly evaluate 960 people when a fire broke out on Lingyun Mountain near the area, 12 December 2019.

The DJI Mavic 2 Enterprise Dual (M2ED) was flown out within minutes of the response team's arrival at the incident for fast situational awareness. Two minutes later, the Matrice 210 V2 drone platform was launched, giving detailed information with its sensor's 30 times zooming ability. The Mavic gave responders their quick incident overlook, while the Matrice provided detailed, high-resolution images for thorough situational awareness. The combination saved more lives, protected firefighters, and shaved firefighting costs.

As Los Angeles Fire Department (LAFD) Battalion Chief Richard Fields, program coordinator, told the Board of Fire Commissioners in a March 2019 report, "Timely and accurate communication is essential in getting the right resources in place to mitigate an incident."

Drones have gained a foothold in the sphere of public safety and forward-looking government agencies are expanding their use in areas including environmental services, public works, transportation and rescue services.
